

## ABSTRACT OF THE DISCLOSURE

A method of manufacturing a semiconductor device is provided that can suppress impurity concentration reduction in a doped channel region arising from formation of a gate insulating film. With a silicon oxide film (20) and a silicon nitride film (21) being formed, p-type impurity ions (23<sub>1</sub>, 23<sub>2</sub>) are implanted in a Y direction from diagonally above. As for an implant angle  $\alpha$  of the ion implantation, an implant angle is adopted that satisfies the relationship  $\tan^{-1}(W2/T) < \alpha \leq \tan^{-1}(W1/T)$ , where W1 is an interval between a first portion (21<sub>1</sub>) and a fourth portion (21<sub>4</sub>) and an interval between a third portion (21<sub>3</sub>) and a sixth portion (21<sub>6</sub>); W2 is an interval between a second portion (21<sub>2</sub>) and a fifth portion (21<sub>5</sub>); T is a total film thickness of the silicon oxide film (20) and the silicon nitride film (21). When the implant angle  $\alpha$  is controlled within that range, impurity ions (23<sub>1</sub>, 23<sub>2</sub>) are implanted into a second side surface (10A<sub>2</sub>) and a fifth side surface (10A<sub>5</sub>) through a silicon oxide film (13).
